1. Supplementary Material

Environmental parameters. Temperature and salinity were determined immediately upon sampling in an on-board bucket by YSI (Yellow Springs, OH, USA). Chlorophyll a concentrations were determined via triplicate 0.5-1 L filtrations onto GF/F filter, frozen at -80°C and extracted with 90% acetone and analyzed fluorometrically. Daily averages for precipitation, and wind speed were downloaded from <http://www.wunderground.com/weather-forecast/US/CA/Catalina.html>. Wave height was collected from the National Buoy Data Center from a buoy located in the San Pedro Channel (33°37' N 118° 19' W), 11 km from our sampling location. Nutrient analyses were performed at the Marine Science Institute Analytical Laboratory in Santa Barbara, CA, with recognized standard oceanographic protocols for nutrient autoanalyzers using a Lachat QuickChem 800 Flow Injection Nutrient Analyzer (Johnson et al, 1985).

Library preparation. Nested PCR (first amplifying with short barcoded 18S-only primers, then reamplifying with primers containing sequencing adapters) was required to amplify all samples, as we were unsuccessful attempting to create sequence-ready material when using the full-length primers alone. For the first PCR, 18S rDNA primers (V4F and V4RB) were used without adding adapters, barcodes/indexes and sequencing primers. This PCR consisted of an initial denaturation at 98°C for 1 min, 10 cycles of 30 s at 98°C, 30 s at 53°C and 30 s at 72°C, followed by 15 cycles of 10 s at 98°C, 30 s at 48°C, 30 s at 72°C, and a final extension at 72°C for 10 min. Nested PCR with different annealing temperatures was used to compensate the considerably lower annealing of the reverse primer compared to the forward primer (Stoeck et al. 2010; Balzano et al. 2015). 1 µL of the PCR product was used as a template for the second PCR, using the modified primers described above. The PCR conditions were: initial denaturation at 98°C for 1 min, 10 cycles of

30 s at 98°C, 30 s at 48°C, 30 s at 72°C, and a final extension at 72°C for 10 min. PCR reactions were then cleaned and concentrated with 1x (vol:vol) Agencourt AMPure XP magnetic beads (Beckman Coulter). Purified products from samples were pooled in equimolar concentrations. The pool was sent to the University of California Davis Genome Center and sequenced with generic sequencing primers on Illumina Miseq 2x300 chemistry.

Canonical Correspondence Analysis (CCA). To investigate the relationships between protist community composition and measured environmental variables, the CCA has been used (ter Braak, 1990). This ordination technique has been chosen rather than RDA (Redundancy Analysis) after a preliminary test performed with Detrended Correspondence Analysis which showed that species response to the selected environmental was unimodal and not linear ($p > 0.05$) (Ramette, 2007).

Different variables were submitted to the forward selection procedure, in which the statistical significance of the term was tested by the unrestricted Monte Carlo permutation test (999 permutations). Explanatory variables with p-values greater than 0.05, were excluded from further analyses. The obtained ordination axes (based on community composition data) are linear combinations of environmental variables that best explain archaeal community structure data.

Variation partitioning was used to evaluate whether pure chemical variables affected the eukaryote community independently of the effect of physical variables. All explanatory variables were divided into three groups. Firstly, we separated the ‘pure bottom-up’ (A) effect as referring to the control by resources, including nutrients (nitrates + nitrites ($\text{NO}_3^- + \text{NO}_2^-$)), orthophosphates (PO_4^{3-}), silicate (SiO_3^{2-}). Secondly, we separated ‘other chemical variables’ (B) (pH) from the pure bottom-up variables. Thirdly, we generated a set of variables related to physical regulation

(Temperature, degree), dominant wave period (DPD, s); direction from which DPD is coming (MWD, degree), significant wave height (WVHT, m), average wave period (APD seconds), Wrigley wind speed average (WSPD, Kmph), Wrigley precipitation sum (cm) (Wrigley refers to the weather station at Wrigley Marine Science Center which is about 20km away from the sampling location). Each group of explanatory variables was tested independently as well as in combination. Additionally, Spearman's rank pairwise correlations between the environmental variables mentioned above helped to determine their significance for further ecological analysis.

Network analysis. Network characterization (structural cohesion and robustness) were evaluated using different topological indexes: degree, betweenness centrality and closeness centrality:

- **Degree** is the number of direct edges linked to the node n .
- **Betweenness centrality (B_n)** of the node n , defined as $B_n = \sum_{j,k} (\delta(j,n,k)/\delta(j,k))$, where j and k are nodes in the network different from the n , $\delta(j,k)$ is the total number of shortest path between j and k and $\delta(j,k,n)$ is the total number of shortest path between j and k that n lies on. Betweenness centrality of a node reflects the centrality of this node as direct route between two other nodes in the network (Yoon et al, 2006).
- **Closeness centrality $C_c(n)$** of a node n is defined as the reciprocal of the average shortest path length and is computed as follows: $C_c(n) = 1 / \text{avg}(L(n,m))$, where $L(n,m)$ is the length of the shortest path between two nodes n and m (Newman, 2005). The closeness centrality measures how fast information spreads from n node to other reachable nodes in the network.

2. Supplementary Figures

Figure S1. Rank abundance curves of the 30 most abundant 18S OTUs generated from both Balzano and Stoeck primers showing strong difference in the relative abundance of Haptophytes OTUs (indicated with the symbol “*” on the plots)

Figure S2. Temporal dynamics of environmental variables at SPOT location during the studied period.

Figure S3. Power-Law degree distribution of protist network indicating the number of OTUs (i.e. nodes) with the specific k degree (for $k=1, 2, \dots, 40$).

Figure S4. Association networks showing the highest correlations between eukaryotic OTUs (Spearman correlation ≥ 0.8 ; $p < 0.01$; $q < 0.05$). Nodes colors and shapes correspond to main protist groups and their ecological behavior respectively.

Figure S5. Modular architecture of protist network according to AllegroMCODE analysis. Modules are decreasingly classified according to their score value.

Figure S6. Modules features as identified by AllegroMCODE analysis. Taxonomical abbreviations: A.: Azadinium; Ba.: Bathycoccus; C.: Chrysochromulina; K.: Karenia; L.: Laboea; M.: Minidiscus; Mi.: Micromonas; P.: Prymnesium; Ph.: Phaeocystis; Pi: Picomonas; Pr.: Prorocentrum; Py.: Pyramimonas; S.: Syrachosphaera; St: Strombidium; T.: Teleaulax.

3. Supplementary Tables

*Table S2 and S4 are presented in <http://figshare.com/> and their access links are indicated in the legends.

Table S1. Percentage of coverage of both Balzano and Stoeck primers on different eukaryotes groups, according to SILVA test probe with zero mismatches allowed.

Table S2*. Relative abundance and dynamic of the 300 most abundant OTUs from which all the statistical analysis has been performed. Code correspond to OTU abbreviation name used to identify node in the network (Figure 4). **Data access link:** <https://figshare.com/s/bf322a07e0ff7f4970f9>

Table S3. Taxonomical and inferred ecological properties of the most abundant protist OTUs, each with a relative abundance of >2% in at least one sample. Chloroplastic trophic group point out potential mixotrophy. “na” indicates OTUs that were not available in the network because they did not display significant spearman correlation with other OTUs.

Table S4*. Bray-Curtis dissimilarity index estimated between samples showing the degree of PCC change between consecutive sampling time (days and weeks). **Data access link:** <https://figshare.com/s/39afba10d1cb808b128a>

Table S5. SIMPER results, showing the contribution ratio of most representatives OTUs between the five discriminate clusters.

Table S6. Canonical correspondence analysis of protist community structure data when constrained by nutrient, chemical and physical variables, respectively.

Table S7. General network properties of substructures (A) and (B), generated by Network Analyzer on Cytoscape.

Table S8. Main properties (cluster score, number of nodes, number of edges and OTU identity) of the different clusters discriminated by AllegroMCODE and presented in Figures S5 and S6.

Table S1. Percentage of coverage of both Balzano and Stoeck primers on different eukaryotes groups, according to SILVA test probe with zero mismatches allowed.

Table S6. Canonical correspondence analysis of protist community structure data when constrained by nutrient, chemical and physical variables, respectively.

Environmental variables	Physico-chemical variables		Physical variables		Chemical variables		Nutrient	
p value	0.031		0.137		<0.0001		0.003	
Total Inertia	4.177		4.177		4.177		4.177	
Sum of all canonical eigenvalues	1.297				0.565		0.447	
Explained variance	31.04				13.52		11.29	
Axix	Axis 1	Axis 2	Axis 1	Axis 2	Axis 1	Axis 2	Axis 1	Axis 2
Eigenvalues	0.393	0.240			0.610	0.564	0.360	0.126
Cumulative percentage variance of:								
species data	30.289	48.794			16.900	32.523	17.481	33.464
species-environment relation	9.402	15.147			14.610	28.126	15.507	29.686

Table S7. General network properties of Substructures (A) and (B), generated by Network Analyzer on Cytoscape.

Network characteristics	Substructure A	Substructure B
Diameter	11	10
Short path length	3.93	3.51
Average neighbors	6.76	10.3
Total number of nodes	103	125
Network density	0.07	0.08
Total number of edges	643	348
Number of negative edges	7	11

Table S8. Main properties (cluster score, number of nodes, number of edges and OTU identity) of the different clusters discriminated by AllegroMCODE and presented in Figures S5 and S6.

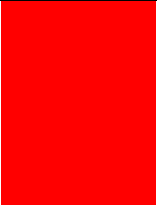

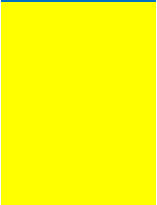

ID	Cluster ID	Nodes colors	Score	Nodes	Edges	Node_IDs
1	Cluster 1		8	18	144	3635_Chrysochromulina_sp.; 1044_Thraustochytriidea_sp.; 4554_Chrysochromulina_sp.; 540_Haptolina_sp.; 2592_Prymnesium_kappa; 3069_Chrysochromulina_acantha_A; 2956_Chrysochromulina_strobilus; 4423_Chrysochromulina_acantha_B; 3657_Phaeocystis_cordata; 6_Chrysochromulina_acantha_C; 4332_Prymnesium_kappa_A; 3618_Prymnesium_Kappa_B; 3896_Syracosphaera_pulchra; 11_Gladiolithus_sp.; 1800_Thraustochytriidea_sp.; 3533_Gladiolithus_sp.; 336_Phaeocystis_sp.; 536_SGII
